1 Introduction

This is an example of RKFIT being used for approximating an artificially created frequency response function $f(z)$ and finding its poles. RKFIT is described in [2, 3] and this code reproduces the example from [2, Section 5.1]. The rational function $f(z)$ is taken from [5, Section 4.1].

2 Problem setup

We first define a rational functions $f(z)$ via its poles, residues, and the linear term. The numbers are taken from [5].

```
pls = [-4500,          -41000,          -100+5000i,  
       -100-5000i,      ...  
        -120+15000i,   -120-15000i,   -3000+35000i, -3000-35000i, ...  
        -200+45000i,   -200-45000i,   -1500+45000i, -1500-45000i, ...  
        -500+70000i,   -500-70000i,   -1000+73000i, -1000-73000i, ...  
        -2000+90000i,  -2000-90000i];  
rsd = [-3000,          -83000,          -5+7000i,  
       -5-7000i,      ...  
        -20+18000i,    -20-18000i,     6000+45000i,  
       6000-45000i,    ...
```

```

40+60000i, 40-60000i, 90+10000i,
90-10000i, ...
50000+80000i, 50000-80000i, 1000+45000i,
1000-45000i, ...
-5000+92000i, -5000-92000i];

pls = pls(:);
rsd = rsd(:);
dd = 0.2; hh = 2e-5;

f = @(zz) arrayfun(@(z) sum(rsd./(z-pls)) + dd + z*hh,zz);

```

The frequency range of interest is 0 to 100 kHz and we can plot the response function easily. The plot should look exactly the same as [5, Figure 1], provided the number of sampling points N is reduced to 100 (in this case some peaks are missed in the plot).

```

figure(1)
N = 200;
zz = 1i*linspace(-1e5, 1e5, N).';
plot(abs(zz)/1e4, abs(f(zz)), 'k-')

```

3 Testing RKFIT

We now run RKFIT from [1] to compute a rational least squares approximant to $f(z)$. To this end we need to "rewrite" the least squares problem in terms of a matrix function acting on a vector, i.e., $\|F\mathbf{b} - r(A)\mathbf{b}\|_2 / \|F\mathbf{b}\|_2 \rightarrow \min$. The

fitting points \mathbf{zz} will be the eigenvalues of a diagonal matrix A , and F will be a diagonal matrix of the fitting values. The vector \mathbf{b} can be used for weighting the data points and we will set all weights equal to one.

```
A = spdiags(zz, 0, N, N);
F = spdiags(f(zz), 0, N, N);
b = ones(N, 1);
```

We also need to specify the initial poles of $r(z)$. By choosing 18 initial poles the rational function to be computed by RKFIT would be of type (18,18). However, the above rational function $f(z)$ is of type (19,18), so we need to increase the numerator degree by $k = 1$. This parameter k , together with the maximal number of iterations to perform, can be given to RKFIT in form of a `param` structure.

```
init = logspace(3,5,9); % initial poles
init = [init , conj(init)];
param.k = 1;
param.maxit = 10;
```

That's it. Now we can run RKFIT.

```
[xi, ratfun, misfit_rkfit] = rkfit(F, A, b, init, param);
```

Here is a convergence plot of RKFIT, showing the relative least squares approximation error after each iteration.

```
figure(2)
semilogy(misfit_rkfit, 'ro--')
hold on
xlabel('iteration')
title('relative 2-norm misfit')
legend('RKFIT')
```

4 The rkfun class

The second output `ratfun` is an object of class `rkfun`. As expected it represents a rational function of type (19,18):

```
ratfun

ratfun =
  RKFUN object of type (19,18).
  Complex Hessenberg pencil (H,K) of size 20-by-19.
  abs(coeffs) = [ 6.24, 6.95, 6.59, 7.13, 6.83, ... 15 more ... ]
```

This rational function $r(z)$ can be evaluated in two ways: The first option is to evaluate a matrix function $r(A)\mathbf{b}$ by calling `ratfun(A,b)` with two input arguments. For example, here we are calculating the relative least squares fitting error, which will coincide (up to roundoff errors) with the misfit of the last RKFIT iterate:

```
format shorte
[norm(F*b - ratfun(A, b))/norm(F*b), misfit_rkfit(end)]

ans =
    3.0126e-14    3.0185e-14
```

Alternatively, we can evaluate $r(z)$ pointwise by giving only one input argument. Let's compare $r(z)$ to $f(z)$ plotted before:

```

figure(1), hold on
plot(abs(zz)/1e4, abs(ratfun(zz)), 'r--')
xlabel('imag(z)/1e4')
title('abs(function value)')
legend('exact', 'RKFIT')

```

One may be interested in the poles of $r(z)$ computed by RKFIT. The poles of an rkfun can be easily retrieved using the `poles` method. Let us compare `poles(ratfun)` to the exact poles of the function $f(z)$.

```

figure(3)
plot(pls, 'ko'), hold on
plot(poles(ratfun), 'r*')
axis([-5e4, 1e4, -1e5, 1e5])
legend('exact poles', 'RKFIT poles', 'Location', 'NorthWest')

```

The agreement between the poles is very good.

5 Some other choices for the initial poles

In practice one may not know the number of poles required to fit a function to a certain accuracy. Let us see what happens if we use too many, in this case 24, initial poles for RKFIT.

```
init24 = logspace(6,9,12);
init24 = [init24 , conj(init24)];

% Rerun RKFIT and plot convergence.
[xi, ratfun, misfit_rkfit24] = rkfit(F, A, b, init24, param);
figure(2)
semilogy(misfit_rkfit24, 'rs--')
```

We may also initialize RKFIT with 18 infinite initial poles, which is a convenient choice if no a priori information about the location of the poles is available.

```
initinf = repmat(inf, 1, 18);

% Rerun RKFIT and plot convergence.
[xi, ratfun, misfit_rkfitinf] = rkfit(F, A, b, initinf, param);
semilogy(misfit_rkfitinf, 'r*--')
xlabel('iteration')
title('relative 2-norm error')
legend('RKFIT, 18 init poles', ...
       'RKFIT, 24 init poles', ...
       'RKFIT, 18 infinite init poles');
axis([1, 10, 1e-15, 1e2])
```

For all three choices of initial poles we find that RKFIT converges within 1 or 2 iterations. In fact, Corollary 3.2 in [3] asserts that RKFIT converges in a single iteration if F is a rational function. It is due to the presence of rounding errors that the convergence is delayed slightly.

6 Comparison with vector fitting

We now compare RKFIT with the vector fitting code described in [4, 5].

The following code makes sure the `vectfit3` implementation of VFIT is on MATLAB's search path, and if it is, defines some options.

```
if exist('vectfit3') ~= 2
    warning('Vector fitting VFIT3 not found in the Matlab path.');
```

```
    warning('VFIT can be downloaded from:')
```

```
    warning('http://www.sintef.no/Projectweb/VECTFIT/Downloads/VFUT3/')
```

```
    warning('Skipping comparison with VFIT3.');
```

```
    return
```

```
end
```

```
xi_vfit = init;           % 18 Initial poles from above
```

```
opts.relax = 1;           % Relaxed non-triviality constraint.
```

```
opts.stable = 0;          % Do not enforce stable poles.
```

```
opts.asymp = 3;           % Options are 1, 2, or 3.
```

```
opts.skip_pole = 0;
```

```
opts.skip_res = 0;
```

```
opts.spy1 = 0;           opts.spy2 = 0;
```

```

opts.logx = 0;      opts.logy = 0;
opts.errplot = 0;  opts.phaseplot = 0;

```

We now run 10 iteration for the 18 and 24 finite poles used before. The VFIT implementation does not allow for infinite poles, as those would lead to Vandermonde matrices.

```

% Use the 18 finite poles as initial guess for VFIT.
for iter = 1:10
    [SER, xi_vfit, rmserr, fit] = ...
        vectfit3(f(zz.'), zz.', xi_vfit, ones(1, N), opts);
    misfit_vfit(iter) = norm(f(zz.') - fit)/norm(F*b);
end

ffit = @(zz) arrayfun(@(z) sum((SER.C).'./(z-diag(SER.A))) ...
    + SER.D + z*SER.E, zz);

figure(1)
plot(abs(zz)/1e4, abs(ffit(zz)), 'b:')
xlabel('imag(z)/1e4')
title('abs(function value)')
legend('exact', 'RKFIT', 'VFIT', 'Location', 'NorthWest')
figure(2), hold on
semilogy(misfit_vfit, 'bo:')
legend('RKFIT', 'VFIT')
figure(3)
plot(xi_vfit, 'bx')
legend('exact poles', 'RKFIT poles', 'VFIT poles', ...
    'Location', 'NorthWest');

% Use the 24 poles as initial guess for VFIT.
xi_vfit = init24;
for iter = 1:10
    [SER, xi_vfit, rmserr, fit] = ...
        vectfit3(f(zz.'), zz.', xi_vfit, ones(1,N), opts);
    misfit_vfit24(iter) = norm(f(zz.') - fit)/norm(F*b);
end

% And plot the errors.
figure(2)
semilogy(misfit_vfit24, 'bs:')
legend('RKFIT, 18 init poles', ...
    'RKFIT, 24 init poles', ...
    'RKFIT, 18 infinite init poles', ...
    'VFIT, 18 init poles', ...
    'VFIT, 24 init poles');

```

This is the end of this example. The following is just to create a nice thumbnail.

```
figure(1), plot(NaN)
```
